Php cast class to subclass

Php cast class to subclass

Anastasionico.uka A couple of days ago, a colleague of mine showed me a TV commercial that was aired on TV a few years ago. The point in question belonged to a well-known chain of British supermarkets and told of an episode that really happened on Christmas Day during the First World War. The soldiers and the German soldiers after months of conflict came out of the trenches and made a truce with a lot of laughs and soccer games, I must admit that those few seconds were enough to brighten up my day and make me think about how the people of those times spent the days of this time of year. During the conversation following the video, I realized that in those times despite the obvious reasons I don't need to mention, there was an incredible technological advance, just think about the movie â ¬ ÅThe imitation game "by Morten Tyldum. I think the same is true for PHP, improvements, even small ones, to the language, the syntax and the code in general always bring good humor and hope in the fact that during th. and months, even years to come, they can make us better programmers and create applications that make us and our customers happy. This year the team responsible for the upgrades managed to deliver some but decisive changes, some of the new features had been the new features Required for years, others are pleasant surprises like those we will receive from our loved ones during the holidays, like those that, on Christmas Day were received by soldiers. In this post, you will learn which features will be implemented in the second part of arm PhP 7.3 and its Christmas GitftSif you haven't read the other parts Yetyou can check the other Blog posts by following the links below 2. Introduction to PHP 7.3 and new syntax, is New features of PHP 7.3, is Drecation and changes - Å Not has yet published, take the eBook if you want to read it NOWNEW Features json throw on erornot having a proper way to handle Rs error When using JSON it was a problem for a long time, and the web developer around the world saw this as a huge drop in language, the RFC of PHP 7.3 accepted this upgrade by a 23 vs 0 vote which says how much this feature was required until PHP V7.2 We needed to use an alternative solution to get an error from JSON and it was not reliable nor competent in its work here is an example: json last error () === json error none // the Result is "Syntax Error" Yes, we can determine if JSON had an error, but, this is clearly not the best way to do it. The new flag I am about to show is excellent alternative because confer to the programmer To use the power of exceptions that can be managed within the code block A ¢ â, ¬ A ¢ â, ¬ A ¢ â, ¬ B variable, should we?: Use JSonException; Try {\$ JSON THTHROW ON ERROR); RETURN BASE64 CODE (\$ JSON);} Catch (JSonException \$ e) {New Shooting New Do not encrypt the data. ', 0, \$ e);} How can you see from the previous code The JSON ENCODE function now has an optional parameter JSON THROW ON ERROR This will capture the error and display it using the following exception methods: \$ and-> getcode (); // Like JSON LAST ERROR () The default adaptation of PHP7.3 to your existing code will be neutral and since it is an optional parameter after updating your PHP everything will still work as expected. This is one of the most important features of the update, so if you want to dig and learn more about taking a look at the official RFC for JSON THROW ON ERRORIS COUNTABOLTABLE A COUNTERED ITEM can be a variable with an array format or an object whose class is Implementing the accounting interface. Last year PHP 7.2 added a notice that occurs every time the web developer counted or tried to get around an indisputable element. You can solve this problem and one of the best solutions currently used is to apply a control like a snippet below: If (is array (\$ santa) ||| \$ santa Countable Instance) {///A Santa is Drawn} The code controls if the variable is an array or is an instance of the accounting interface. And it will work, but it looks a bit â € œCresolloâ € and like many of you working long hours, after a while seeing this kind of lines wear eyes out. The team that is developing the new version has taken into account this and added a new feature that will help the web developer immensely. The IS Countable function takes a variable as a parameter and then returns a boolean depending on whether the function can be dumped or not. There is no restriction on the format the parameter must be, of course, if you put a variable that is not converted the return will be false. Let's see it in practice (is countable (\$ santa)) {// \$ santa is convertible} This snippet basically makes the grevious one, but it is much easier to remember and more important for me more readable. Not to mention this function can be used as shown or in a condomal ternary operator that will seem even more satisfactory. For more information on IS Countable, take a look at the official RFCARRAY KEY FIRST (), ARRAY KEY LAST () AS FOR PHP version 5.6, there are over 75 integrated functions that belong to the array we need to get all the keys using array keys () and only then go for the first or last array values. Another way is to opt for the end () or reset (). As you can know, all the methods just described by changing the array pointer, which is something that (besides being consumers of resources) simply can't to do. The next version RFC proposed the introduction of 4 new methods that have been set to resolve this problem. The four methods were: array key first () array value first () array key first () array value first () array valu 1\$last = array_key_last (\$reindeers); // \$last is equal to 9This is an example of associativoy arrays:\$first = array_key_first (\$reindeers); // \$last is equal to «Rudolph»\$last = array_key_first is equal to «Blitzen»The same would work for the other two functions illustrated in this array_value_*Only to be clear, I repeat, These functions have In my opinion, these two functions would have been useful but according to different web developers, in some cases the value first (\$reindeers): // \$first is equal to null\$last = array value last (\$reindeers): // \$first is equal to null\$nother option I found by browsing the forums and talking to other web developers was to return a tupla of the type [\$key => \$value]. Although this option will not be available in the new version, given the favorable responses, it could arrive with the following RFCs. to compatibility issues, the only problem could arise if you created and are using your version of array key first () and array key last (). The implementation of a secure application must always be the main objective of each programmer. A task that each of us has to face daily to reduce the risk of CSRF attacks and loss of information. Same cooking site declares that cookies must be sent only on request initiated by the same domain. This is not an official standard but Google Chrome and some of the best PHP frameworks implement it already while Firefox and the new version of other frameworks have confirmed they want to do it. Here is the support scheme for cookies on the same site from caniuse.comAttually, cookies are issued by the set-cookie header, One web developer can Set a key-value pair next to the browser flags in order to decide whether a cookie should be available or not. This way of doing things allows vulnerable access to CSRF attacks. The new RFC adds supposes to solve the problem by adding a new parameter and also modifying four main functions of the language.setcookiesetrawcookie [,\$value [,\$expire [,\$path [,\$domain [,\$secure [,\$httponly [,\$samesite]]]]]);]]); Two ways have been proposed: add a new topic to the function or allow an array of options to move all cookies options inside. How will that work? Two values can be added to the same flag of the site present in the functions mentioned above. Cookies using Lax will be accessible in a GET request from another domain, while Strict will not be accessibleun Get Get instance, the header when using a looser flag will be similar to this: set-cookies: key = value; path = /; Domain = example.org; Httponly; Members = Includes features that increase security in the code always seem a no-game for boys but as always before deciding to apply them in our scripts we must correctly evaluate Pro and Cons of our choice as the main risk implied for using the same flag of the site An additional argument to such functions is that it could never become an official standard. It means that the browser will eventually reduce the flag. If this happens and you have already implemented it, it will provoke your applications stuffed with the junk code that must be removed. My personal advice is to wait to see what will happen. If this flag becomes more used and eventually defined as a standard go for it! Speaking of backward changes, like most of the previous changes seen in this article. Be a problem When you implement it in your code. Conclusions I anticipated this new version does not involve changes in breaking, since it is not a new version, it is right this way, php is taking small but Points accounts that allow it to progress and improve over time despite the fact that over the years people have changed in more fashionable programming languages. In the next post, you will see other various changes and a list of features no longer in use being deprecated to make room for new projects. If the content of these posts you liked and do not want to wait, the full article in a single format is available as Kindle on Amazon in the link below. This post Blog is a section of the book Kindle ât cePhp 7.3 and its Christmas gifts "Now it's your Turnnow I want to hear you; are you satisfied with the new functionality brought by the language? What are you going to use most often? Let me know by leaving a guick comment below. Join Hacker Mezzogiorno
